

# Modular Arithmetic and Division

## Quotient- Remainder Theorem:

Given positive integers  $a$  and  $d$ , there exist integers  $q$  and  $r$  such that,

$$a = dq + r, \quad r < d$$

$q = a \text{ div } d$                       Example:  $30 \text{ div } 7 = 4$   
 $r = a \text{ mod } d$                        $30 \text{ mod } 7 = 2$

## Greatest Common Divisor:

The GCD for integers  $a$  and  $b$  the largest integer that divides both  $a$  and  $b$ . To efficiently find the greatest common divisor you can use the Euclidean Algorithm.

Two lemmas are needed:

1.  $\text{gcd}(r, 0) = r$
2. If  $a = dq + r$ , then  $\text{gcd}(a, d) = \text{gcd}(d, r)$

**Example:** Find  $\text{gcd}(408, 120)$

$$\begin{aligned} \text{gcd}(408, 120) &= \text{gcd}(120, 48) \\ &= \text{gcd}(48, 24) \\ &= \text{gcd}(24, 0) \\ &= 24 \end{aligned}$$

$$\begin{aligned} 408 &= 3 \times 120 + 48 \\ 120 &= 2 \times 48 + 24 \\ 48 &= 2 \times 24 + 0 \end{aligned}$$

sample rough work

$$\begin{array}{r} 3 \\ 120 \overline{) 408} \\ \underline{- 360} \\ 48 \end{array}$$

**Practice:** Practice: Find  $\text{gcd}(5280, 1360)$  using the Euclidean Algorithm. Answer: 80

The algorithm helps to reduce larger computations into smaller ones and this is also a benefit of modular arithmetic.

**Congruence:**  $a \equiv b \pmod{n}$ ,  $a$  and  $b$  are congruent modulo  $n$  if they have the same remainders when divided by  $n$

**Examples:**  $30 \equiv 2 \pmod{7}$ ,  $9 \equiv 1 \pmod{2}$ ,  $21 \equiv 5 \pmod{8}$ , etc.

## Modular Equivalences:

For the integers  $a$ ,  $q$ ,  $r$ , and  $d > 0$ , the following statements are equivalent:

1.  $a = dq + r$
2.  $a \equiv r \pmod{d}$
3.  $a \pmod{d} = r \pmod{d}$
4.  $d \mid (a - r)$
5.  $a$  and  $r$  have the same (nonnegative) remainder when divided by  $d$

## Modular Arithmetic:

Let  $a, b, c, d,$  and  $n$  be integers with  $n > 1$  where  $a \equiv c \pmod{n}$  and  $b \equiv d \pmod{n}$ , then

1.  $ab \equiv [(a \bmod n)(b \bmod n)] \bmod n$
2.  $(a+b) \equiv (c+d) \pmod{n}$
3.  $a^k \equiv c^k \pmod{n}$  for all integers  $k$
4.  $a^k \pmod{n} = (a \bmod n)^k \bmod n$
5. If  $p$  is prime and  $a$  is not divisible by  $p$ ,  $a^{(p-1)} \equiv 1 \pmod{p}$  [Fermat's Little Theorem]

Use modular arithmetic in the following examples to convert large number computations into smaller number computations. It can be beneficial to do this in cryptography for example, when the numbers can be over a thousand digits long, taking up more memory and time.

**Tip:** When using a calculator to compute the remainder, use the formula:

$$a \bmod n = a - d \cdot \left\lfloor \frac{a}{n} \right\rfloor$$

**Example:**  $103 \bmod 12 = 103 - 12 \left\lfloor \frac{103}{12} \right\rfloor = 103 - 12(8) = 7$

Some examples using modular arithmetic:

1.  $(3-20) \bmod 5 = 3 \bmod 5 - 20 \bmod 5 = 3 - 0 = 3$  or since  $-17 = -4 \cdot (5) + 3$
2.  $-8 \equiv 2 \pmod{5}$  since  $-8 = -2 \cdot (5) + 2$
3.  $(12+8) \bmod 5 = 0$  or we can say  $(12 + 8) \bmod 5 \equiv 0 \pmod{5}$
4. Since  $26 \bmod 4 = 2$ ,  $26^2 \bmod 4 \equiv 2^2 \bmod 4 = 20 \bmod 4 = 0$

Using Fermat's Little Theorem:

$$\begin{aligned} 5. \quad & 4^{17} \pmod{11} \\ & = 4^{(10+7)} \pmod{11} \\ & = 4^{10} 4^7 \pmod{11} && 4^{10} \equiv 1 \pmod{11} = 1 \text{ since } 11 \text{ is prime} \\ & \equiv 4^{2+2+2+1} \pmod{11} \\ & \equiv 4^2 4^2 4^2 4^1 \pmod{11} \\ & \equiv 5 \cdot 5 \cdot 5 \cdot 4 \pmod{11} \\ & = 125 \cdot 4 \pmod{11} \\ & \equiv 4 \cdot 4 \pmod{11} \\ & \equiv 5 \pmod{11} \end{aligned}$$

So,  $4^{17} \pmod{11} = 5$

6. **Practice:** Show that  $3^{26} \bmod 5 = 4$
